

## Step-1

Consider the following matrix:

$$A = \begin{bmatrix} a & -0.8 \\ 0.8 & 0.2 \end{bmatrix}$$

To obtain its eigenvalues, solve  $\det(A - \lambda I) = 0$ . This gives,

$$\begin{aligned} 0 &= \begin{vmatrix} a - \lambda & -0.8 \\ 0.8 & 0.2 - \lambda \end{vmatrix} \\ &= (a - \lambda)(0.2 - \lambda) + 0.64 \\ &= \lambda^2 - (0.2 + a)\lambda + 0.2a + 0.64 \end{aligned}$$

## Step-2

Consider the equation,  $\lambda^2 - (0.2 + a)\lambda + 0.2a + 0.64 = 0$ .

Thus,

$$\begin{aligned} \lambda &= \frac{(0.2 + a) \pm \sqrt{(0.2 + a)^2 - 4(0.2a + 0.64)}}{2} \\ &= \frac{(0.2 + a) \pm \sqrt{(0.04 + 0.4a + a^2) - (0.8a + 2.56)}}{2} \\ &= \frac{(0.2 + a) \pm \sqrt{a^2 - 0.4a - 2.52}}{2} \end{aligned}$$

## Step-3

Since  $|\lambda_i| < 1$ , we get the following:

$$\begin{aligned} -2 &< (0.2 + a) \pm \sqrt{a^2 - 0.4a - 2.52} < 2 \\ -2.2 &< a \pm \sqrt{a^2 - 0.4a - 2.52} < 1.98 \\ -2.2 - a &< \pm \sqrt{a^2 - 0.4a - 2.52} < 1.98 - a \\ (-2.2 - a)^2 &< a^2 - 0.4a - 2.52 < (1.98 - a)^2 \end{aligned}$$

Simplifying, we get

$$\begin{aligned}
 a^2 + 4.4a + 4.84 &< a^2 - 0.4a - 2.52 < a^2 - 3.96a + 3.9204 \\
 4.4a + 4.84 &< -0.4a - 2.52 < -3.96a + 3.9204 \\
 4.4a + 7.36 &< -0.4a < -3.96a + 6.4404 \\
 -11a - 18.4 &> a > 9.9a - 16.101
 \end{aligned}$$

## Step-4

Consider the two inequalities separately.

$$\begin{aligned}
 -11a - 18.4 &> a \\
 -18.4 &> 12a \\
 \frac{-18.4}{12} &> a \\
 -1.533 &> a \\
 a &> 9.9a - 16.101 \\
 -8.9a &> -16.101 \\
 a &< \frac{16.101}{8.9} \\
 a &< 1.809
 \end{aligned}$$

## Step-5

Thus, if matrix  $A$  has to be stable,  $a < -1.533$ .

If the matrix  $A$  has to be neutrally stable, some of its eigenvalues satisfy  $|\lambda_i| = 1$  and other eigenvalues satisfy  $|\lambda_i| < 1$ .

This gives,  $a = 1.809$  or  $a = -1.533$ .

Consider the following matrix:

$$B = \begin{bmatrix} b & 0.8 \\ 0 & 0.2 \end{bmatrix}$$

To obtain its eigenvalues, solve  $\det(B - \lambda I) = 0$ . This gives,

$$\begin{aligned}
 0 &= \begin{vmatrix} b - \lambda & 0.8 \\ 0 & 0.2 - \lambda \end{vmatrix} \\
 &= (b - \lambda)(0.2 - \lambda) + 0 \\
 &= \lambda^2 - (0.2 + b)\lambda + 0.2b
 \end{aligned}$$

## Step-6

Consider the equation  $\lambda^2 - (0.2 + b)\lambda + 0.2b = 0$ .

Thus,

$$\begin{aligned}\lambda &= \frac{(0.2 + b) \pm \sqrt{(0.2 + b)^2 - 0.8b}}{2} \\ &= \frac{(0.2 + b) \pm \sqrt{b^2 + 0.4b + 0.04 - 0.8b}}{2} \\ &= \frac{(0.2 + b) \pm \sqrt{b^2 - 0.4b + 0.04}}{2} \\ \lambda &= \frac{(0.2 + b) \pm \sqrt{(b - 0.2)^2}}{2} \\ &= \frac{(0.2 + b) \pm (b - 0.2)}{2} \\ &= b \text{ or } 0.2\end{aligned}$$

## Step-7

For the matrix  $B$  to be stable, we want  $|\lambda_i| < 1$ . Therefore,  $\boxed{b < 1}$ .

For the matrix  $B$  to be neutrally stable, we want some eigenvalue  $\hat{\lambda}$  such that  $|\lambda_i| = 1$  and other  $\hat{\lambda}$  such that  $|\lambda_i| < 1$ . Therefore,  $\boxed{b = 1}$ .

## Step-8

Consider the following matrix:

$$C = \begin{bmatrix} c & 0.8 \\ 0.2 & c \end{bmatrix}$$

To obtain its eigenvalues, solve  $\det(C - \lambda I) = 0$ . This gives,

$$\begin{aligned}0 &= \begin{vmatrix} c - \lambda & 0.8 \\ 0.2 & c - \lambda \end{vmatrix} \\ &= (c - \lambda)^2 - 0.16 \\ &= \lambda^2 - 2c\lambda + (c^2 - 0.16)\end{aligned}$$

## Step-9

Consider the equation  $\lambda^2 - 2c\lambda + (c^2 - 0.16) = 0$ .

Thus,

$$\begin{aligned}\lambda &= \frac{2c \pm \sqrt{4c^2 - 4(c^2 - 0.16)}}{2} \\ &= \frac{2c \pm \sqrt{0.64}}{2} \\ &= \frac{2c \pm 0.8}{2} \\ &= c \pm 0.4\end{aligned}$$

## Step-10

For the matrix  $C$  to be stable, we want  $|\lambda_i| < 1$ . Therefore,  $\boxed{-0.6 < c < 0.6}$ .

For the matrix  $C$  to be neutrally stable, we want some eigenvalue  $\hat{\lambda}$  such that  $|\lambda_i| = 1$  and other  $\hat{\lambda}$  such that  $|\lambda_i| < 1$ . Therefore,  $\boxed{-0.6 \leq c \leq 0.6}$ .
