## TESTS FOR POSITIVE DEFINITENESS (正定性的判定)

Tests for Positive Definiteness  
 Positive Semidefinite Matrices  
 Tests for Negative Definiteness  
 The Principal Axes Theorem  
 The Law of Inertia  
 Diagonalization by Congruence

A quadratic form (二次型) is a homogeneous polynomial of degree two in a number of variables (二次齐次多项式).

For example,  $4x^2 + 2xy - 3y^2$  is a quadratic form in the variables  $x$  and  $y$ .

quadratic curve  
(二次曲线)

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

Ellipse  
(椭圆)

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$$

Hyperbola  
(双曲线)

# I. Tests for Positive Definiteness (正定性的判定)

Let  $A = \begin{bmatrix} a & b \\ b & c \end{bmatrix}$ , and the corresponding quadratic form is

$f(x, y) = \mathbf{x}^T A \mathbf{x} = ax^2 + 2bxy + cy^2$ . When is it positive definite?

$$f(x, y) = a \left( x + \frac{b}{a} y \right)^2 + \frac{ac - b^2}{a} y^2$$

So  $A$  is positive definite when  $a > 0$  and  $ac - b^2 > 0$ .

From those conditions, *both eigenvalues are positive*.

(Hint: check the determinant and the trace)

It also shows that *two pivots are also positive*.

(Hint:  $\begin{bmatrix} a & b \\ b & c \end{bmatrix} \rightarrow \begin{bmatrix} a & b \\ 0 & (ac - b^2)/a \end{bmatrix}$ )

However, it is not enough to require that the determinant of  $\mathbf{A}$  is positive. For example,  $\begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}$  has positive determinant, but  $\mathbf{A}$  is negative definite (负定).

The determinant test is applied not only to  $\mathbf{A}$  itself, giving  $ac - b^2 > 0$ , but also to the 1 by 1 submatrix  $a$  in the upper left-hand corner.

$$\mathbf{A} = \begin{bmatrix} a & b \\ b & c \end{bmatrix}$$

**Both leading submatrices:**  $\mathbf{A}_1 = [a]$ ,  $\mathbf{A}_2 = \begin{bmatrix} a & b \\ b & c \end{bmatrix}$  need to have positive determinant to ensure the positive definiteness of the matrix  $\mathbf{A}$ .

If  $\mathbf{A} = \begin{bmatrix} 2 & 2 & -2 \\ 2 & 3 & -2 \\ -2 & -2 & 4 \end{bmatrix}.$

**The 3 leading submatrices:**

$$\mathbf{A}_1 = [2], \quad \mathbf{A}_2 = \begin{bmatrix} 2 & 2 \\ 2 & 3 \end{bmatrix}, \quad \mathbf{A}_3 = \begin{bmatrix} 2 & 2 & -2 \\ 2 & 3 & -2 \\ -2 & -2 & 4 \end{bmatrix}.$$

Let  $A$  be a matrix of degree  $n$ , and let  $A_k$  be the leading submatrix (*upper left submatrices*) of degree  $k$ , consisting of the entries of  $A$  in the **first  $k$  rows and first  $k$  columns**.

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1k} & a_{1k+1} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2k} & a_{2k+1} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} & a_{kk+1} & \cdots & a_{kn} \\ a_{k+11} & a_{k+12} & \cdots & a_{k+1k} & a_{k+1k+1} & \cdots & a_{k+1n} \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nk} & a_{nk+1} & \cdots & a_{nn} \end{bmatrix}$$

$$A_k = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1k} \\ a_{21} & a_{22} & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} \end{bmatrix}$$

□ If  $A = LDU$ , then  $A_k = L_k D_k U_k$ , and  $|A_k| = d_1 d_2 \cdots d_k$ .

**Formula for pivots:**  $d_k = \frac{|A_k|}{|A_{k-1}|}$

Here is the main theorem on *positive definiteness*, and a reasonably detailed proof.

**Theorem 1 (Test for *positive definiteness*, Part I)** Each of the following tests is a necessary and sufficient condition for the real symmetric matrix  $\mathbf{A}$  to be *positive definite*:

(正定性判别： 以下是判定一个实对称矩阵 $\mathbf{A}$ 正定的充要条件)

(I)  $\mathbf{x}^T \mathbf{A} \mathbf{x} > 0$  for all nonzero real vectors  $\mathbf{x}$ . (Definition)

(II) All the eigenvalues of  $\mathbf{A}$  satisfy  $\lambda_i > 0$ .

(III) All the upper left submatrices  $\mathbf{A}_k$  have positive determinants.

(IV) All the pivots (without row exchanges) satisfy  $d_k > 0$ .

**Proof :**

**Proof (I)**  $\mathbf{x}^T \mathbf{A} \mathbf{x} > 0$  for all nonzero real vectors  $\mathbf{x}$ .

(II) All the eigenvalues of  $\mathbf{A}$  satisfy  $\lambda_i > 0$ .

(I)  $\Rightarrow$  (II): If  $\mathbf{A} \mathbf{x} = \lambda \mathbf{x}$ , then  $\mathbf{x}^T \mathbf{A} \mathbf{x} = \mathbf{x}^T \lambda \mathbf{x} = \lambda \|\mathbf{x}\|^2$ .

A positive definite matrix has positive eigenvalues, since  $\mathbf{x}^T \mathbf{A} \mathbf{x} > 0$  for  $\mathbf{x} \neq \mathbf{0}$ .

(II)  $\Rightarrow$  (I): Since real symmetric matrices have a full set of orthonormal eigenvectors (denoted by  $\mathbf{x}_1, \dots, \mathbf{x}_n$ ), any  $\mathbf{x}$  is a combination  $c_1 \mathbf{x}_1 + \dots + c_n \mathbf{x}_n$ . Then

$$\mathbf{A} \mathbf{x} = c_1 \mathbf{A} \mathbf{x}_1 + \dots + c_n \mathbf{A} \mathbf{x}_n = c_1 \lambda_1 \mathbf{x}_1 + \dots + c_n \lambda_n \mathbf{x}_n.$$

Because of the orthogonality  $\mathbf{x}_i^T \mathbf{x}_j = 0$  ( $i \neq j$ ), and the normalization  $\mathbf{x}_i^T \mathbf{x}_i = 1$ ,

$$\begin{aligned} \mathbf{x}^T \mathbf{A} \mathbf{x} &= (c_1 \mathbf{x}_1^T + \dots + c_n \mathbf{x}_n^T)(c_1 \lambda_1 \mathbf{x}_1 + \dots + c_n \lambda_n \mathbf{x}_n) \\ &= c_1^2 \lambda_1 + \dots + c_n^2 \lambda_n. \end{aligned}$$

If every  $\lambda_i > 0$ , then this equation shows that  $\mathbf{x}^T \mathbf{A} \mathbf{x} > 0$ .

**Proof (I)**  $\mathbf{x}^T \mathbf{A} \mathbf{x} > 0$  for all nonzero real vectors  $\mathbf{x}$ .

(III) All the upper left submatrices  $\mathbf{A}_k$  have positive determinants.

(I)  $\Rightarrow$  (III): The determinant of  $\mathbf{A}$  is the product of the eigenvalues.

And if condition I holds, we already know that these eigenvalues are positive.

But we also have to deal with *every* upper left submatrix  $\mathbf{A}_k$ . The *trick* is to look at all nonzero vectors whose last  $n - k$  components are zero:

$$\mathbf{x}^T \mathbf{A} \mathbf{x} = [\mathbf{x}_k^T \quad \mathbf{0}] \begin{bmatrix} \mathbf{A}_k & * \\ * & * \end{bmatrix} \begin{bmatrix} \mathbf{x}_k \\ \mathbf{0} \end{bmatrix} = \mathbf{x}_k^T \mathbf{A}_k \mathbf{x}_k > 0.$$

Thus  $\mathbf{A}_k$  is positive definite. Its eigenvalues (not the same  $\lambda_i$ ) must be positive. Its determinant is their product, so all upper left determinants are positive.

That means: *If condition I holds, so does condition III.*

**Proof (I)**  $\mathbf{x}^T \mathbf{A} \mathbf{x} > 0$  for all nonzero real vectors  $\mathbf{x}$ .

(III) All the upper left submatrices  $\mathbf{A}_k$  have positive determinants.

(IV) All the pivots (without row exchanges) satisfy  $d_k > 0$ .

(III)  $\rightarrow$  (IV): According to the formula for pivots, the  $k$ th pivot  $d_k$  is the ratio of  $\det \mathbf{A}_k$  to  $\det \mathbf{A}_{k-1}$ .

If the determinants are all positive, so are the pivots.

(IV)  $\rightarrow$  (I):  $\mathbf{A}$  is real symmetric, then  $\mathbf{A} = \mathbf{L} \mathbf{D} \mathbf{L}^T$  where  $\mathbf{L}$  is lower triangular, with 1's on the diagonal, and  $\mathbf{D} = \text{diag}(d_1, d_2, \dots, d_n)$ .

$$\mathbf{x}^T \mathbf{A} \mathbf{x} = \mathbf{x}^T (\mathbf{L} \mathbf{D} \mathbf{L}^T) \mathbf{x} = (\mathbf{L}^T \mathbf{x})^T \mathbf{D} (\mathbf{L}^T \mathbf{x})$$

Let  $\mathbf{y} = \mathbf{L}^T \mathbf{x} = [y_1 \ y_2 \ \cdots \ y_n]^T$ , then  $\mathbf{x} \neq \mathbf{0} \Rightarrow \mathbf{y} \neq \mathbf{0}$  since  $\mathbf{L}$  is invertible.

$$\mathbf{x}^T \mathbf{A} \mathbf{x} = \mathbf{y}^T \mathbf{D} \mathbf{y} = d_1 y_1^2 + d_2 y_2^2 + \cdots + d_n y_n^2 > 0, \forall \mathbf{x} \neq \mathbf{0}.$$

We illustrate the idea by giving an example.

**Example 2**  $\mathbf{A} = \begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 2 \end{bmatrix}.$

**Example 2**  $A = \begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 2 \end{bmatrix}$  has positive pivots 2,  $\frac{3}{2}$ , and  $\frac{4}{3}$ .

$$A = \begin{bmatrix} 1 & 0 & 0 \\ -\frac{1}{2} & 1 & 0 \\ 0 & -\frac{2}{3} & 1 \end{bmatrix} \begin{bmatrix} 2 & & \\ & \frac{3}{2} & \\ & & \frac{4}{3} \end{bmatrix} \begin{bmatrix} 1 & -\frac{1}{2} & 0 \\ 0 & 1 & -\frac{2}{3} \\ 0 & 0 & 1 \end{bmatrix} = \mathbf{LDL}^T.$$

$$\text{If } \mathbf{x} = \begin{bmatrix} u \\ v \\ w \end{bmatrix}, \text{ then } \mathbf{L}^T \mathbf{x} = \begin{bmatrix} 1 & -\frac{1}{2} & 0 \\ 0 & 1 & -\frac{2}{3} \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} u \\ v \\ w \end{bmatrix} = \begin{bmatrix} u - \frac{1}{2}v \\ v - \frac{2}{3}w \\ w \end{bmatrix}.$$

$$\text{So } \mathbf{x}^T \mathbf{A} \mathbf{x} = \mathbf{x}^T \mathbf{LDL}^T \mathbf{x} = (\mathbf{L}^T \mathbf{x})^T \mathbf{D} (\mathbf{L}^T \mathbf{x})$$

$$= 2 \left( u - \frac{1}{2}v \right)^2 + \frac{3}{2} \left( v - \frac{2}{3}w \right)^2 + \frac{4}{3}w^2.$$

Those positive pivots in  $\mathbf{D}$  multiply perfect squares to make  $\mathbf{x}^T \mathbf{A} \mathbf{x}$  positive.

**Example 2** Test the positive definiteness of the matrix

$$\mathbf{A} = \begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 2 \end{bmatrix},$$

Each of the following tests is enough by itself. (选用任何一种即可)

- (1) **Pivot test:**  $\mathbf{A}$  has positive pivots  $d_1 = 2$ ,  $d_2 = \frac{3}{2}$ , and  $d_3 = \frac{4}{3}$ .
- (2) **Determinant test:** Each of the upper left submatrices has positive determinant:  $|\mathbf{A}_1| = 2$ ,  $|\mathbf{A}_2| = 3$ , and  $|\mathbf{A}_3| = |\mathbf{A}| = 4$ .  
(We can also see that  $d_k = |\mathbf{A}_k|/|\mathbf{A}_{k-1}|$ .)
- (3) **Eigenvalue test:** The eigenvalues of  $\mathbf{A}$  are  $\lambda_1 = 2 - \sqrt{2}$ ,  $\lambda_2 = 2$ , and  $\lambda_3 = 2 + \sqrt{2}$ .

So *by any means*, we can conclude that  $\mathbf{A}$  is positive definite.

**Theorem 1 (Test for *positive definiteness*, Part II)** Each of the following tests is a necessary and sufficient condition for the real symmetric matrix  $A$  to be *positive definite*:

(V) There is a matrix  $R$  with independent columns such that  $A = R^T R$ .

**Proof.** (V)  $\Rightarrow$  (I): The key is to recognize

$$\mathbf{x}^T A \mathbf{x} = \mathbf{x}^T R^T R \mathbf{x} = (R \mathbf{x})^T (R \mathbf{x}) = \|R \mathbf{x}\|^2.$$

This squared length  $\|R \mathbf{x}\|^2$  is positive (unless  $\mathbf{x} = \mathbf{0}$ ), because  $R$  has independent columns. (If  $\mathbf{x}$  is nonzero then  $R \mathbf{x}$  is nonzero.)

Thus  $\mathbf{x}^T R^T R \mathbf{x} > 0$  and  $R^T R$  is positive definite.

(I)  $\Rightarrow$  (V): Since  $A$  is real symmetric,  $A$  can be decomposed into

$$A = Q \Lambda Q^T = (Q \sqrt{\Lambda})(\sqrt{\Lambda} Q^T),$$

So take  $R = \sqrt{\Lambda} Q^T$ .

(Another choice is  $R = Q \sqrt{\Lambda} Q^T$ , the symmetric positive definite square root of  $A$ .)

## II. Positive Semidefinite matrices (半正定矩阵)

**Definition 2** A quadratic form  $f(\mathbf{x}) = \mathbf{x}^T \mathbf{A} \mathbf{x}$  is:

- **positive definite** if  $f(\mathbf{x}) > 0$  for all  $\mathbf{x} \neq \mathbf{0}$ ;
- **negative definite** if  $f(\mathbf{x}) < 0$  for all  $\mathbf{x} \neq \mathbf{0}$ ;
- **indefinite** if  $f(\mathbf{x})$  assumes both positive and negative values (既有正值又有负值);
- **positive semidefinite (半正定)** if  $f(\mathbf{x}) \geq 0$  for all  $\mathbf{x}$ ;
- **negative semidefinite** if  $f(\mathbf{x}) \leq 0$  for all  $\mathbf{x}$ .

How to test the **positive semidefiniteness**?

The main point is to see the **analogies** with the positive definite case.

(半正定性的判定: 类比正定性)

**Theorem 2** Each of the following tests is a necessary and sufficient condition for a symmetric matrix  $A$  to be *positive semidefinite*:

(I')  $\mathbf{x}^T A \mathbf{x} \geq 0$  for all vectors  $\mathbf{x}$ . (This defines positive semidefinite)

(II') All the eigenvalues of  $A$  satisfy  $\lambda_i \geq 0$ .

(III') No **principal submatrices** (主子矩阵) have negative determinants.

(IV') No pivots are negative.

(V') There is a matrix  $R$ , **possibly with dependent columns**, such that  $A = R^T R$ .

**Remark** The diagonalization  $A = Q \Lambda Q^T$  leads to  $\mathbf{x}^T A \mathbf{x} = \mathbf{x}^T Q \Lambda Q^T \mathbf{x} = \mathbf{y}^T \Lambda \mathbf{y}$ , where  $\mathbf{y} = Q^T \mathbf{x}$ .

If  $A$  has rank  $r$ , there are  $r$  nonzero  $\lambda$ 's and  $r$  perfect squares in  $\mathbf{y}^T \Lambda \mathbf{y} = \lambda_1 y_1^2 + \cdots + \lambda_r y_r^2$ . (We will come back to discuss this later)

## Principal Submatrix

Let  $\mathbf{A}$  be an  $n \times n$  matrix. A  $k \times k$  submatrix of  $\mathbf{A}$  formed by deleting  $n - k$  rows of  $\mathbf{A}$ , and the **same**  $n - k$  columns of  $\mathbf{A}$ , is called **principal submatrix** (主子矩阵) of  $\mathbf{A}$ . The determinant of a principal submatrix of  $\mathbf{A}$  is called a **principal minor** (主子式) of  $\mathbf{A}$ .

(Note that the definition does not specify which  $n - k$  rows and columns to delete, only that *their indices must be the same*.)

For example,  $\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$ .

First order principal submatrices:  $[a_{11}]$ ,  $[a_{22}]$ ,  $[a_{33}]$ .

Second order principal submatrices:  $\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$ ,  $\begin{bmatrix} a_{11} & a_{13} \\ a_{31} & a_{33} \end{bmatrix}$ ,  $\begin{bmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{bmatrix}$ .

Third order principal submatrix:  $\mathbf{A}$ .

(III') No principal submatrices have negative determinants.

**Note** Condition (III') applies to all the **principal** submatrices, not only those in the **upper left-hand corner** (leading principal submatrices).

(判定半正定性时, 不仅要检查**左上角各阶主子矩阵**的行列式, 即**顺序主子式**, 而且**检查所有各阶主子矩阵**的行列式即**主子式**)

Otherwise, we could not distinguish between two matrices whose upper left determinants were all zero:

$\begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}$  is positive semidefinite;

$\begin{bmatrix} 0 & 0 \\ 0 & -1 \end{bmatrix}$  is negative semidefinite.

**Example 3** Show the positive *semidefiniteness* of the following matrix by all five tests. (任选一种都是充分的)

$$\mathbf{A} = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 2 & -2 \\ 0 & -2 & 4 \end{bmatrix},$$

□ (I')

$$\mathbf{x}^T \mathbf{A} \mathbf{x} = x_1^2 + 2x_2^2 + 4x_3^2 + 2x_1x_2 - 4x_2x_3 = (x_1 + x_2)^2 + (x_2 - 2x_3)^2 \geq 0 \quad (\text{zero if } -x_1 = x_2 = 2x_3)$$

□ (II') The eigenvalues are  $\lambda_1 = 0$ ,  $\lambda_2 = (7 - \sqrt{13})/2$ ,  $\lambda_3 = (7 + \sqrt{13})/2$  (a zero eigenvalue).

□ (III') All **principal** submatrices

$$\begin{array}{c} 1, 2, 4 \\ \left| \begin{smallmatrix} 1 & 1 \\ 1 & 2 \end{smallmatrix} \right| = 1, \quad \left| \begin{smallmatrix} 1 & 0 \\ 0 & 4 \end{smallmatrix} \right| = 4, \quad \left| \begin{smallmatrix} 2 & -2 \\ -2 & 4 \end{smallmatrix} \right| = 4, \\ |A| = 0. \end{array}$$

**Example 3** Show the positive *semidefiniteness* of the following matrix by all five tests. (任选一种都是充分的)

$$\mathbf{A} = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 2 & -2 \\ 0 & -2 & 4 \end{bmatrix},$$

□ (IV')  $\mathbf{A} \rightarrow \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & -2 \\ 0 & -2 & 4 \end{bmatrix} \rightarrow \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & -2 \\ 0 & 0 & 0 \end{bmatrix}$  (*missing pivot*)

□ (V')  $\mathbf{A} = \mathbf{R}^T \mathbf{R}$  with dependent columns in the matrix  $\mathbf{R}$ :

$$\mathbf{A} = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 0 & -2 & 0 \end{bmatrix} \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & -2 \\ 0 & 0 & 0 \end{bmatrix}.$$

Therefore, *by any means*, we can conclude that  $\mathbf{A}$  is positive semidefinite.

### III. Tests for Negative Definiteness

**Theorem 3** The following statements are equivalent for a real symmetric matrix  $A$  of degree  $n$ :

- (I)  $\mathbf{x}^T A \mathbf{x} < 0$  for all nonzero real vectors  $\mathbf{x}$ . (Definition)
- (II) All the eigenvalues of  $A$  satisfy  $\lambda_i < 0$ .
- (III) The determinants of the upper left submatrices  $A_k$  are negative for odd  $k$  and positive for even  $k$ . ( $A$  的奇数阶顺序主子式都小于零, 偶数阶顺序主子式都大于零)
- (IV) All the pivots (without row exchanges) satisfy  $d_k < 0$ .
- (V) There is a matrix  $R$  with independent columns such that  $A = -R^T R$ .

# IV. The Principal Axes Theorem (主轴定理)

$$\frac{5}{4}x^2 + \frac{5}{4}y^2 - \frac{3}{2}xy = 1$$

“消除交叉项”

$$\frac{x'^2}{2} + 2y'^2 = 1$$

$$\frac{1}{2}\left(\frac{\sqrt{2}}{2}x + \frac{\sqrt{2}}{2}y\right)^2 + 2\left(\frac{\sqrt{2}}{2}x - \frac{\sqrt{2}}{2}y\right)^2 = 1$$

$$\begin{cases} x = \frac{\sqrt{2}}{2}x' - \frac{\sqrt{2}}{2}y' \\ y = \frac{\sqrt{2}}{2}x' + \frac{\sqrt{2}}{2}y' \end{cases}$$

“改斜归正”

换

## Change of Variable (变量替换) in a Quadratic Form

If  $\mathbf{x}$  represents a variable vector in  $\mathbf{R}^n$ , then a **change of variable** is an equation of the form

$$\mathbf{x} = \mathbf{C}\mathbf{y}, \text{ or equivalently, } \mathbf{y} = \mathbf{C}^{-1}\mathbf{x} \quad (1)$$

where  $\mathbf{C}$  is an invertible matrix and  $\mathbf{y}$  is a new variable vector in  $\mathbf{R}^n$ .

Here  $\mathbf{y}$  is the coordinate vector of  $\mathbf{x}$  relative to the basis of  $\mathbf{R}^n$  determined by the columns of  $\mathbf{C}$ .

If the change of variable (1) is made in a quadratic form  $\mathbf{x}^T \mathbf{A} \mathbf{x}$ , then

$$\mathbf{x}^T \mathbf{A} \mathbf{x} = (\mathbf{C}\mathbf{y})^T \mathbf{A} (\mathbf{C}\mathbf{y}) = \mathbf{y}^T \mathbf{C}^T \mathbf{A} \mathbf{C} \mathbf{y} = \mathbf{y}^T (\mathbf{C}^T \mathbf{A} \mathbf{C}) \mathbf{y} \quad (2)$$

and the new matrix of the quadratic form is  $\mathbf{C}^T \mathbf{A} \mathbf{C}$ .

**Definition 3** For an invertible matrix  $\mathbf{C}$ , the linear transformation  $\mathbf{A} \rightarrow \mathbf{C}^T \mathbf{A} \mathbf{C}$  is called a **congruence transformation** (合同变换),

which transforms the vector  $\mathbf{y}$  to the vector  $\mathbf{x} = \mathbf{C}\mathbf{y}$ , and the quadratic form  $\mathbf{x}^T \mathbf{A} \mathbf{x}$  to the quadratic form  $\mathbf{y}^T \mathbf{C}^T \mathbf{A} \mathbf{C} \mathbf{y}$ .

When  $A$  is **real symmetric**:  $Q^{-1}AQ = \Lambda = Q^T A Q$

$$Q = \begin{bmatrix} | & | & \cdots & | \\ x_1 & x_2 & \cdots & x_n \\ | & | & \cdots & | \\ | & | & \cdots & | \end{bmatrix}, \quad \Lambda = \begin{bmatrix} \lambda_1 & & & \\ & \lambda_2 & & \\ & & \ddots & \\ & & & \lambda_n \end{bmatrix}.$$

$Q$ : orthogonal matrix

$x_1, \dots, x_n$ : orthonormal eigenvectors

$\lambda_1, \dots, \lambda_n$ : real eigenvalues

Since  $A$  in the quadratic form is real symmetric, the Spectral Theorem guarantees the following theorem.

### Theorem 4 (*The Principal Axes Theorem*, 主轴定理)

Let  $A$  be an  $n \times n$  real symmetric matrix. Then there is an **orthogonal** change of variable,  $\mathbf{x} = Q\mathbf{y}$  (i.e.,  $Q$  is an *orthogonal* matrix), that transforms the quadratic form  $\mathbf{x}^T A \mathbf{x}$  into a quadratic form  $\mathbf{y}^T \Lambda \mathbf{y}$  with no cross-product term (不含交叉乘积项) (i.e.,  $\Lambda$  is a diagonal matrix).

$$\mathbf{x}^T A \mathbf{x} = \mathbf{y}^T \Lambda \mathbf{y} = \lambda_1 y_1^2 + \cdots + \lambda_n y_n^2 \text{ (二次型的标准形),}$$

where  $\lambda_1, \dots, \lambda_n$  are eigenvalues of  $A$ , and their orthonormal eigenvectors go into the columns of  $Q$ . ( $Q^T A Q = \Lambda$ )

## A Geometric View of Principal Axes

It can be shown that the set of all  $\mathbf{x}$  in  $\mathbf{R}^2$  that satisfy

$$\mathbf{x}^T \mathbf{A} \mathbf{x} = c \quad (c \text{ is a constant})$$

either corresponds to an ellipse (or circle), a hyperbola, two intersecting lines, or a single point, or contains no points at all.

If  $\mathbf{A}$  is a diagonal matrix, the graph is in *standard position*, such as in the figure below.

$$\frac{x_1^2}{a^2} + \frac{x_2^2}{b^2} = 1, \quad a > b > 0$$

ellipse

$$\frac{x_1^2}{a^2} - \frac{x_2^2}{b^2} = 1, \quad a > b > 0$$

hyperbola

## A Geometric View of Principal Axes

If  $A$  is not a diagonal matrix, the graph is rotated out of standard position, as in the figure below.

$$(a) 5x_1^2 - 4x_1x_2 + 5x_2^2 = 48$$

$$(b) x_1^2 - 8x_1x_2 - 5x_2^2 = 16$$

Finding the **principal axes** (determined by the eigenvectors of  $A$ ) amounts to finding a new coordinate system with respect to which the graph is in standard position.

**Example 4(a)** Let  $\mathbf{A} = \begin{bmatrix} 5 & -2 \\ -2 & 5 \end{bmatrix}$ , and  $\mathbf{x}^T \mathbf{A} \mathbf{x} = 5x_1^2 - 4x_1x_2 + 5x_2^2$ .

The eigenvalues of  $\mathbf{A}$  are 3 and 7, with corresponding unit eigenvectors

$$\mathbf{u}_1 = \begin{bmatrix} 1/\sqrt{2} \\ 1/\sqrt{2} \end{bmatrix}, \mathbf{u}_2 = \begin{bmatrix} -1/\sqrt{2} \\ 1/\sqrt{2} \end{bmatrix}.$$

$$\text{Let } \mathbf{Q} = [\mathbf{u}_1 \quad \mathbf{u}_2] = \begin{bmatrix} 1/\sqrt{2} & -1/\sqrt{2} \\ 1/\sqrt{2} & 1/\sqrt{2} \end{bmatrix}.$$

Then  $\mathbf{Q}$  orthogonally diagonalizes  $\mathbf{A}$ ,

so the change of variable  $\mathbf{x} = \mathbf{Q} \mathbf{y}$  produces

the quadratic form  $\mathbf{y}^T \mathbf{\Lambda} \mathbf{y} = 3y_1^2 + 7y_2^2$ .

$$(a) \ 5x_1^2 - 4x_1x_2 + 5x_2^2 = 48$$

**Example 4(b)** Let  $\mathbf{A} = \begin{bmatrix} 1 & -4 \\ -4 & -5 \end{bmatrix}$ , and  $\mathbf{x}^T \mathbf{A} \mathbf{x} = x_1^2 - 8x_1x_2 - 5x_2^2$ .

The eigenvalues of  $\mathbf{A}$  are 3 and  $-7$ , with corresponding unit

eigenvectors  $\mathbf{u}_1 = \begin{bmatrix} 2/\sqrt{5} \\ -1/\sqrt{5} \end{bmatrix}$ ,  $\mathbf{u}_2 = \begin{bmatrix} 1/\sqrt{5} \\ 2/\sqrt{5} \end{bmatrix}$ .

Let  $\mathbf{Q} = [\mathbf{u}_1 \quad \mathbf{u}_2] = \begin{bmatrix} 2/\sqrt{5} & 1/\sqrt{5} \\ -1/\sqrt{5} & 2/\sqrt{5} \end{bmatrix}$ .

Then  $\mathbf{Q}$  orthogonally diagonalizes  $\mathbf{A}$ ,

so the change of variable  $\mathbf{x} = \mathbf{Q} \mathbf{y}$  produces

the quadratic form  $\mathbf{y}^T \mathbf{\Lambda} \mathbf{y} = 3y_1^2 - 7y_2^2$ .

$$(b) \ x_1^2 - 8x_1x_2 - 5x_2^2 = 16$$

## The Principal Axes Theorem in $n$ dimensions

**Example 5**  $\mathbf{x}^T \mathbf{A} \mathbf{x} = 2x_1^2 + 4x_1x_2 - 4x_1x_3 + 5x_2^2 - 8x_2x_3 + 5x_3^2$

Converting this quadratic form into a standard form is just the same as:

(See Section 5.5 Example 2) Let  $\mathbf{A} = \begin{bmatrix} 2 & 2 & -2 \\ 2 & 5 & -4 \\ -2 & -4 & 5 \end{bmatrix}$ .

Find an orthogonal matrix  $\mathbf{Q}$  such that  $\mathbf{Q}^{-1} \mathbf{A} \mathbf{Q}$  is a diagonal matrix.

$$\mathbf{Q} = [\boldsymbol{\gamma}_1, \boldsymbol{\gamma}_2, \boldsymbol{\gamma}_3] = \begin{bmatrix} -2\sqrt{5}/5 & 2\sqrt{5}/15 & 1/3 \\ \sqrt{5}/5 & 4\sqrt{5}/15 & 2/3 \\ 0 & \sqrt{5}/3 & -2/3 \end{bmatrix} \quad \text{and} \quad \mathbf{Q}^{-1} \mathbf{A} \mathbf{Q} = \mathbf{Q}^T \mathbf{A} \mathbf{Q} = \begin{bmatrix} 1 & & \\ & 1 & \\ & & 10 \end{bmatrix}.$$

So

$$\mathbf{y}^T \mathbf{A} \mathbf{y} = y_1^2 + y_2^2 + 10y_3^2$$

**Application:** The quadric surface (二次曲面):

$$2x_1^2 + 4x_1x_2 - 4x_1x_3 + 5x_2^2 - 8x_2x_3 + 5x_3^2 = 1$$

has changed to

$$y_1^2 + y_2^2 + 10y_3^2 = 1$$

with respect to a new basis  $\{\boldsymbol{y}_1, \boldsymbol{y}_2, \boldsymbol{y}_3\}$ .

This is an equation of ellipsoid (椭球面), whose axes have half-lengths

$$\frac{1}{\sqrt{|\lambda_1|}} = 1, \frac{1}{\sqrt{|\lambda_2|}} = 1, \frac{1}{\sqrt{|\lambda_3|}} = \frac{1}{\sqrt{10}}.$$

**Remark** Suppose  $\boldsymbol{A} = \boldsymbol{Q}\boldsymbol{\Lambda}\boldsymbol{Q}^T$  ( $\boldsymbol{A}$  is  $n \times n$ ) with  $\lambda_i > 0$ . Rotating  $\boldsymbol{y} = \boldsymbol{Q}^T \boldsymbol{x}$  simplifies  $\boldsymbol{x}^T \boldsymbol{A} \boldsymbol{x} = 1$ :

$$\boldsymbol{x}^T \boldsymbol{Q} \boldsymbol{\Lambda} \boldsymbol{Q}^T \boldsymbol{x} = \boldsymbol{y}^T \boldsymbol{\Lambda} \boldsymbol{y} = 1 = \lambda_1 y_1^2 + \cdots + \lambda_n y_n^2 = 1.$$

This is the equation of an ellipsoid. Its axes have *half*-lengths

$\frac{1}{\sqrt{\lambda_1}}, \dots, \frac{1}{\sqrt{\lambda_n}}$  from the center. In the original  $\boldsymbol{x}$ -space they point along the eigenvectors of  $\boldsymbol{A}$ .

$$2x_1^2 + 4x_1x_2 - 4x_1x_3 + 5x_2^2 - 8x_2x_3 + 5x_3^2 = 1$$

$$y_1^2 + y_2^2 + 10y_3^2 = 1$$

特征值的符号决定了二次曲面的类型

# *hyperboloid of one sheet* (单叶双曲面)

Standard equation:

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1$$

柯西指出：当方程是标准型时, 二次曲面用二次项的符号来进行分类.

## Quadratic equation (二次方程)

A quadratic equation in  $n$  variables  $x_1, x_2, \dots, x_n$  is one of the form

$$\mathbf{x}^T \mathbf{A} \mathbf{x} + \mathbf{B} \mathbf{x} + \alpha = 0,$$

where  $\mathbf{x} = (x_1, x_2, \dots, x_n)^T$ ,  $\mathbf{A}$  is an  $n \times n$  symmetric matrix,  $\mathbf{B}$  is a  $1 \times n$  matrix, and  $\alpha$  is a scalar.

The vector function  $f(\mathbf{x}) = \mathbf{x}^T \mathbf{A} \mathbf{x}$  is the quadratic form in  $n$  variables associated with the quadratic equation.

In the case of *three* unknowns, if

$$\mathbf{x} = \begin{pmatrix} x \\ y \\ z \end{pmatrix}, \quad \mathbf{A} = \begin{pmatrix} a & d & e \\ d & b & f \\ e & f & c \end{pmatrix}, \quad \mathbf{B} = (g \quad h \quad i),$$

then the quadratic equation is

$$ax^2 + by^2 + cz^2 + 2dxy + 2exz + 2fyz + gx + hy + iz + \alpha = 0.$$

The graph of a quadratic equation in three variables is called a **quadric surface (二次曲面)**.

## Some typical quadric surfaces (常见二次曲面分类)

1. Ellipsoid (椭球面)
2. Hyperboloid of one sheet (单叶双曲面)
3. Hyperboloid of two sheets (双叶双曲面)
4. Elliptic paraboloid (椭圆抛物面)
5. Hyperbolic paraboloid (双曲抛物面)
6. Double cone (圆锥面)

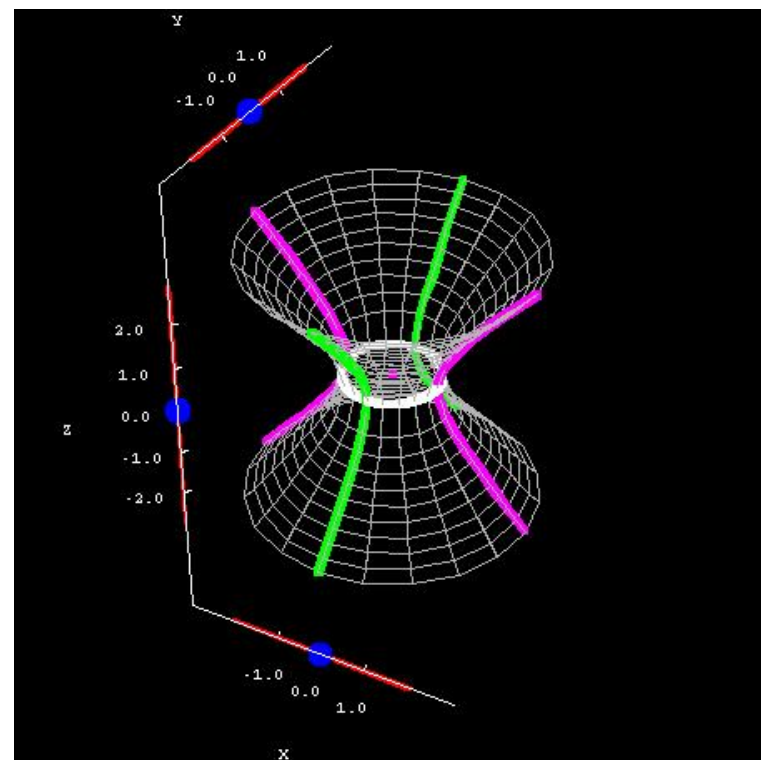

# 1. Ellipsoid (椭球面)

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1 \quad (a, b, c > 0)$$

## 2. Hyperboloid of one sheet (单叶双曲面)

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1 \quad (a, b, c > 0)$$

### 3. Hyperboloid of two sheets (双叶双曲面)

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1 \quad (a, b, c > 0)$$

## 4. Elliptic paraboloid (椭圆抛物面)

$$\frac{x^2}{2p} + \frac{y^2}{2q} = z,$$

where  $p, q$  have the same sign.

## 5. Hyperbolic paraboloid (双曲抛物面)

$$\frac{x^2}{2p} - \frac{y^2}{2q} = z,$$

where  $p, q$  have the same sign.

(a)

(b)

## 6. Double cone (圆锥面)

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 0 \quad (a, b, c > 0)$$

## V. The Law of Inertia (惯性定律)

Matrix A	Operations (变换)	Matrix B	Invariants (不变量)
$A$ is any $m \times n$ matrix	Elementary operations	$B = PAQ$ (where $P$ and $Q$ are invertible $m \times m$ and $n \times n$ matrices)	Rank
$A$ is any $n \times n$ matrix	Similarity transformation (相似变换)	$B = M^{-1}AM$ (where $M$ is an invertible $n \times n$ matrix)	Eigenvalues; Determinant; Trace; Rank
$A$ is any real symmetric $n \times n$ matrix	Congruence transformation (合同变换)	$B = C^TAC$ (where $C$ is an invertible $n \times n$ matrix)	Symmetry; Rank; Number of positive eigenvalues, negative eigenvalues, and zero eigenvalues

## Theorem 5 (*Sylvester's law of inertia*)

$C^T A C$  has the same number of positive eigenvalues, negative eigenvalues, and zero eigenvalues as  $A$ , where  $C$  is a *nonsingular* matrix.

[在化简成标准型时, 为何总是得到同样数目的正项和负项?

(正惯性指数、负惯性指数)

西尔维斯特 (James Joseph Sylvester, 英国数学家, 1814-1897) 给出了二次型的惯性定律, 但没证明.

该定律后被雅可比 (Jacobi, Carl Gustav Jacob, 德国数学家, 1804-1851) 重新发现和证明.]

**Remark.**

For any real symmetric matrix  $A$ , *the signs of the pivots agree with the signs of the eigenvalues*. The eigenvalue matrix  $\Lambda$  and the pivot matrix  $D$  have the same number of positive entries, negative entries, and zero entries.

(We will assume that  $A$  allows the symmetric factorization  $A = LDL^T$  (without row exchanges).

By the law of inertia,  $A$  has the same number of positive eigenvalues as  $D$ .

But the eigenvalues of  $D$  are just its diagonal entries (the pivots). Thus the number of positive pivots matches the number of positive eigenvalues of  $A$ .)

*That is both beautiful and practical. (brings together pivots and eigenvalues; uses pivots to locate eigenvalues)*

**Example 6 (a)** Suppose  $A = I$ .

Then  $C^T A C = C^T C$  is positive definite.

Both  $I$  and  $C^T C$  have  $n$  positive eigenvalues, confirming the law of inertia.

**Example 6 (b)** If  $A = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$ ,

then  $C^T A C$  has a negative determinant:

$$|C^T A C| = |C^T| \cdot |A| \cdot |C| = -|C|^2 < 0,$$

therefore  $C^T A C$  must have one positive and one negative eigenvalue, like  $A$ .

# VI. Diagonalization by Congruence Transformation

## [补充：合同变换法(初等变换法)化二次型为标准形]

任何可逆矩阵可表示为一系列初等矩阵的乘积.

**思路：** 任意一个 $n$ 阶实对称矩阵 $A$ , 都可以通过一系列相同类型的初等行、列变换化成对角矩阵.

$$C^T A C = \text{diag}(d_1, \dots, d_n)$$

设  $C = P_1 P_2 \dots P_k$ ,

**定理** 对任意一个 $n$ 阶实对称矩阵 $A$ , 都存在可逆矩阵 $C$ , 使得  $C^T A C = \text{diag}(d_1, d_2, \dots, d_n)$ .

**析** 设  $A$  是  $n$  阶实对称矩阵.

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}$$

**(1)** 如果  $a_{11} \neq 0$ , 由于  $a_{1j} = a_{j1} (j=1, 2, \dots, n)$ , 因此对  $A$  做相同类型的行、列倍加变换, 可将第 1 行与第 1 列的其他元素全化为零, 得

$$C^T A C = \begin{bmatrix} a_{11} & \mathbf{0} \\ \mathbf{0} & A_1 \end{bmatrix}$$

其中  $A_1$  仍为  $n-1$  阶实对称矩阵.

(2) 如果  $a_{11}=0$ , 但存在  $a_{ii} \neq 0$ , 先将第1列与第*i*列对换, 第1行与第*i*行对换, 就把  $a_{ii}$  换到第1行第1列的位置, 化为(1).

(3) 如果  $a_{ii}=0 (i=1, 2, \dots, n)$ ,  $\exists a_{ij} \neq 0$ , 可将第*j*列加到第*i*列, 将第*j*行加到第*i*行, 第*i*行第*i*列的元素化为  $2a_{ij} \neq 0$ , 就化为(2).

用数学归纳法可以证明: 对任一个  $n$  阶实对称矩阵  $A$ , 都存在初等矩阵  $P_1, P_2, \dots, P_k$ , 使得

$$P_k^T \cdots P_2^T P_1^T A P_1 P_2 \cdots P_k = C^T A C = \text{diag}(d_1, d_2, \dots, d_n),$$

其中  $C = P_1 P_2 \cdots P_k = I P_1 P_2 \cdots P_k$

即对  $A$  做的列变换同样施加于单位矩阵  $I$ , 即得变换矩阵  $C$ .

## The Principal Axes Theorem in $n$ dimensions

**Recall Example 5**  $\mathbf{x}^T \mathbf{A} \mathbf{x} = 2x_1^2 + 4x_1x_2 - 4x_1x_3 + 5x_2^2 - 8x_2x_3 + 5x_3^2$

Converting this quadratic form into a standard form is just the same as:

(See Section 5.5 Example 2) Let  $\mathbf{A} = \begin{bmatrix} 2 & 2 & -2 \\ 2 & 5 & -4 \\ -2 & -4 & 5 \end{bmatrix}$ .

Find an orthogonal matrix  $\mathbf{Q}$  such that  $\mathbf{Q}^{-1} \mathbf{A} \mathbf{Q}$  is a diagonal matrix.

$$\mathbf{Q} = [\boldsymbol{\gamma}_1, \boldsymbol{\gamma}_2, \boldsymbol{\gamma}_3] = \begin{bmatrix} -2\sqrt{5}/5 & 2\sqrt{5}/15 & 1/3 \\ \sqrt{5}/5 & 4\sqrt{5}/15 & 2/3 \\ 0 & \sqrt{5}/3 & -2/3 \end{bmatrix} \quad \text{and} \quad \mathbf{Q}^{-1} \mathbf{A} \mathbf{Q} = \mathbf{Q}^T \mathbf{A} \mathbf{Q} = \begin{bmatrix} 1 & & \\ & 1 & \\ & & 10 \end{bmatrix}.$$

So

$$\mathbf{y}^T \mathbf{A} \mathbf{y} = y_1^2 + y_2^2 + 10y_3^2$$

**例** 用初等变换法将Example 5的二次型

$$f(x_1, x_2, x_3) = 2x_1^2 + 4x_1x_2 - 4x_1x_3 + 5x_2^2 - 8x_2x_3 + 5x_3^2$$

化为标准形, 并求所做的坐标变换  $\mathbf{x} = \mathbf{C}\mathbf{y}$  的变换矩阵  $\mathbf{C}$ .

**解** 将二次型的矩阵  $\mathbf{A}$  与单位矩阵  $\mathbf{I}$  上下排列, 对  $\mathbf{A}$  做相同类型的初等行、列变换使之化为对角阵, 同样的初等列变换, 将  $\mathbf{I}$  化为  $\mathbf{C}$ .

(以下  $\mathbf{c}_i$ ,  $\mathbf{r}_i$  分别表示 第  $i$  列, 第  $i$  行)

$$\begin{pmatrix} \mathbf{A} \\ \mathbf{I} \end{pmatrix} = \left[ \begin{array}{ccc|ccc} 2 & 2 & -2 & & & \\ 2 & 5 & -4 & & & \\ -2 & -4 & 5 & & & \\ \hline 1 & 0 & 0 & & & \\ 0 & 1 & 0 & & & \\ 0 & 0 & 1 & & & \end{array} \right]$$

$$\begin{array}{l} c_2 + (-1)c_1 \\ c_3 + c_1 \end{array} \longrightarrow \left[ \begin{array}{ccc|ccc} 2 & 0 & 0 & & & \\ 2 & 3 & -2 & & & \\ -2 & -2 & 3 & & & \\ \hline 1 & -1 & 1 & & & \\ 0 & 1 & 0 & & & \\ 0 & 0 & 1 & & & \end{array} \right]$$

$$\begin{array}{l} r_2 + (-1)r_1 \\ r_3 + r_1 \end{array} \longrightarrow \left[ \begin{array}{ccc|ccc} 2 & 0 & 0 & & & \\ 0 & 3 & -2 & & & \\ 0 & -2 & 3 & & & \\ \hline 1 & -1 & 1 & & & \\ 0 & 1 & 0 & & & \\ 0 & 0 & 1 & & & \end{array} \right]$$

no operation

$$\begin{array}{l} c_3 + \frac{2}{3}c_2 \\ r_3 + \frac{2}{3}r_2 \end{array} \longrightarrow \left[ \begin{array}{ccc|ccc} 2 & 0 & 0 & & & \\ 0 & 3 & 0 & & & \\ 0 & 0 & \frac{5}{3} & & & \\ \hline 1 & -1 & \frac{1}{3} & & & \\ 0 & 1 & \frac{2}{3} & & & \\ 0 & 0 & 1 & & & \end{array} \right] = \begin{pmatrix} \mathbf{D} \\ \mathbf{C} \end{pmatrix}$$

上面的变换可用分块矩阵表示,

$$\text{即 } \begin{pmatrix} \mathbf{C}^T & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{pmatrix} \begin{pmatrix} \mathbf{A} \\ \mathbf{I} \end{pmatrix} \mathbf{C} = \begin{pmatrix} \mathbf{C}^T \mathbf{A} \mathbf{C} \\ \mathbf{C} \end{pmatrix} = \begin{pmatrix} \mathbf{D} \\ \mathbf{C} \end{pmatrix}$$

$$\mathbf{C}^T \mathbf{A} \mathbf{C} = \text{diag}(2, 3, \frac{5}{3})$$

做坐标变换  $\mathbf{x} = \mathbf{C}\mathbf{y}$ , 其中  $\mathbf{C} = \begin{bmatrix} 1 & -1 & \frac{1}{3} \\ 0 & 1 & \frac{2}{3} \\ 0 & 0 & 1 \end{bmatrix}$

$$\text{则 } \mathbf{y}^T \mathbf{C}^T \mathbf{A} \mathbf{C} \mathbf{y} = 2y_1^2 + 3y_2^2 + \frac{5}{3}y_3^2$$

**注:** 用正交变换法得到的标准形为  $y_1^2 + y_2^2 + 10y_3^2$ .  
标准形并不唯一! 但标准形的正负号个数是不变量.

**Key words:**
