Part III Growth Theory: The Economy in the Very Long Run

Chapter 8

Economic Growth I: Capital Accumulation and Population Growth

N. Gregory Mankiw, Macroeconomics (10e)

IN THIS CHAPTER, YOU WILL LEARN:

- the closed economy Solow model
- how a country's standard of living depends on its saving and population growth rates
- how to use the “Golden Rule” to find the optimal saving rate and capital stock

Why growth matters

- Data on infant mortality rates:
 - 20% in the poorest 1/5 of all countries
 - 0.4% in the richest 1/5
- In Pakistan, 85% of people live on less than \$2/day.
- One-fourth of the poorest countries have had famines during the past 3 decades.
- Poverty is associated with oppression of women and minorities.

Economic growth raises living standards and reduces poverty....

Income and poverty in the world

selected countries, 2010

links to prepared graphs @ Gapminder.org

notes: circle size is proportional to population size,
color of circle indicates continent, press “play” on
bottom to see the cross section graph evolve over time

Income per capita and

- Life expectancy
- Infant mortality
- Malaria deaths per 100,000
- Cell phone users per 100 people

Why growth matters

- Anything that affects the long-run rate of economic growth – even by a tiny amount – will have huge effects on living standards in the long run.

annual growth rate of income per capita	increase in standard of living after...		
	...25 years	...50 years	...100 years
2.0%	64.0%	169.2%	624.5%
2.5%	85.4%	243.7%	1,081.4%

The lessons of growth theory

...can make a positive difference in the lives of hundreds of millions of people.

These lessons help us

- understand why poor countries are poor
- design policies that can help them grow
- learn how our own growth rate is affected by shocks and our government's policies

8.1 The Accumulation of Capital

The Solow model

- due to **Robert Solow**,
won Nobel Prize for contributions to
the study of economic growth. (1987)
- a major paradigm:
 - widely used in policy making
 - benchmark against which most
recent growth theories are compared
- looks at the determinants of economic growth
and the standard of living **in the long run**

How Solow model is different from Chapter 3's model

$$Y = F(\bar{K}, \bar{L}) \quad C = C(Y - T)$$

1. **K** is no longer fixed:
investment causes it to grow,
depreciation causes it to shrink
2. **L** is no longer fixed:
population growth causes it to grow
3. the consumption function is simpler
a part of income

How Solow model is different from Chapter 3's model

4. no G or T

(only to simplify presentation;
we can still do fiscal policy experiments)

5. cosmetic differences 表现形式不同

(lowercase letters for per-worker magnitudes
instead of uppercase letters for aggregate
magnitudes)

The production function

- In aggregate terms: $Y = F(K, L)$
- Define: $y = Y/L$ = output per worker
 $k = K/L$ = capital per worker

- Assume constant returns to scale:

$$zY = F(zK, zL) \text{ for any } z > 0$$

- Pick $z = 1/L$. Then

$$Y/L = F(K/L, 1)$$

$$y = F(k, 1)$$

$$y = f(k)$$

$$\text{where } f(k) = F(k, 1)$$

The production function

Output per
worker, y

Note: this production function exhibits diminishing MPK.

The national income identity

- $Y = C + I$ (remember, no G) + *closed economy*
(No NX)
- In “per worker” terms:

$$y = c + i$$

where $\underline{c = C/L}$ and $\underline{i = I/L}$
人均消费 人均投资

The consumption function

- s = the saving rate,
the fraction of income that is saved
(s is an exogenous parameter)

Note: s is the only lowercase variable
that is *not equal to*
its uppercase version divided by L

- Consumption function: $c = \underline{(1-s)}y$
(per worker)

Saving and investment

- saving (per worker) $= y - c$
 $= y - (1-s)y$
 $= sy$

- National income identity is $y = c + i$

Rearrange to get: $i = y - c = sy$

(investment = saving, like in chap. 3!)

- Using the results above,

$$i = sy = sf(k)$$

Output, consumption, and investment

Depreciation

Depreciation
per worker, δk

δ = the rate of depreciation

= the fraction of the capital stock
that wears out each period

Capital accumulation

The basic idea: Investment increases the capital stock, depreciation reduces it.

~~Change in capital stock = investment – depreciation~~

$$\Delta k = i - \delta k$$

Since $i = sf(k)$, this becomes:

$$\Delta k = sf(k) - \delta k$$

The equation of motion for k

$$\Delta k = sf(k) - \delta k$$

- The Solow model's central equation
- Determines behavior of capital over time...
- ...which, in turn, determines behavior of all of the other endogenous variables because they all depend on k . E.g.,

income per person: $y = f(k)$

consumption per person: $c = (1 - s)f(k)$

The steady state

$$\Delta k = sf(k) - \delta k$$

If investment is just enough to cover depreciation
[$sf(k) = \delta k$],

then capital per worker will remain constant:

$$\Delta k = 0.$$

This occurs at one value of k , denoted k^* ,
called the **steady state capital stock**.

The steady state

Moving toward the steady state

$$\Delta k = sf(k) - \delta k$$

Moving toward the steady state

$$\Delta k = sf(k) - \delta k$$

Moving toward the steady state

$$\Delta k = sf(k) - \delta k$$

Moving toward the steady state

$$\Delta k = sf(k) - \delta k$$

Moving toward the steady state

$$\Delta k = sf(k) - \delta k$$

Investment
and
depreciation

Summary:

As long as $k < k^*$,
investment will exceed
depreciation,
and k will continue to
grow toward k^* .

NOW YOU TRY

Approaching k^* from above

Draw the Solow model diagram,
labeling the steady state k^* .

On the horizontal axis, pick a value greater than k^*
for the economy's initial capital stock. Label it k_1 .

Show what happens to k over time.

Does k move toward the steady state or
away from it?

Mankiw, *Macroeconomics*, 10e, © 2019 Worth Publishers

A numerical example

Production function (aggregate):

$$\mathbf{Y} = \mathbf{F}(\mathbf{K}, \mathbf{L}) = \sqrt{\mathbf{K} \times \mathbf{L}} = \mathbf{K}^{1/2} \mathbf{L}^{1/2}$$

To derive the per-worker production function, divide through by \mathbf{L} :

$$\frac{\mathbf{Y}}{\mathbf{L}} = \frac{\mathbf{K}^{1/2} \mathbf{L}^{1/2}}{\mathbf{L}} = \left(\frac{\mathbf{K}}{\mathbf{L}} \right)^{1/2}$$

Then substitute $\mathbf{y} = \mathbf{Y}/\mathbf{L}$ and $\mathbf{k} = \mathbf{K}/\mathbf{L}$ to get

$$\mathbf{y} = \mathbf{f}(\mathbf{k}) = \mathbf{k}^{1/2}$$

A numerical example, *cont.*

Assume:

- $s = 0.3$
- $\delta = 0.1$
- initial value of $k = 4.0$

equilibrium

$$\Delta k = s f(k) - \delta k = 0$$

$$0.3 \sqrt{k} = 0.1 k$$

$$k^* = 9$$

Approaching the steady state:

A numerical example

$$s = 0.3, \quad \delta = 0.1$$

Year	k	y	c	i	δk	Δk
1	4.000	2.000	1.400	0.600	0.400	0.200
2	4.200	2.049	1.435	0.615	0.420	0.195
3	4.395	2.096	1.467	0.629	0.440	0.189
4	4.584	2.141	1.499	0.642	0.458	0.184
...						
10	5.602	2.367	1.657	0.710	0.560	0.150
...						
25	7.351	2.706	1.894	0.812	0.732	0.080
...						
100	8.962	2.994	2.096	0.898	0.896	0.002
...						
∞	9.000	3.000	2.100	0.900	0.900	0.000

NOW YOU TRY

Solve for the steady state

Continue to assume

$$s = 0.3, \delta = 0.1, \text{ and } y = k^{1/2}$$

Use the equation of motion

$$\Delta k = s f(k) - \delta k$$

to solve for the steady-state values of k , y , and c .

ANSWERS

Solve for the steady state

$$\Delta \mathbf{k} = 0 \quad \text{definition of steady state}$$

$$\mathbf{s} \mathbf{f}(\mathbf{k}^*) = \delta \mathbf{k}^* \quad \text{eq'n of motion with } \Delta \mathbf{k} = 0$$

$$0.3\sqrt{\mathbf{k}^*} = 0.1\mathbf{k}^* \quad \text{using assumed values}$$

$$3 = \frac{\mathbf{k}^*}{\sqrt{\mathbf{k}^*}} = \sqrt{\mathbf{k}^*}$$

$$\text{Solve to get: } \mathbf{k}^* = 9 \quad \text{and} \quad \mathbf{y}^* = \sqrt{\mathbf{k}^*} = 3$$

$$\text{Finally, } \mathbf{c}^* = (1 - \mathbf{s})\mathbf{y}^* = 0.7 \times 3 = 2.1$$

An increase in the saving rate

An increase in the saving rate raises investment...
...causing k to grow toward a new steady state:

Prediction:

- The Solow model predicts that countries with higher rates of saving and investment will have higher levels of capital and income per worker in the long run.
- Are the data consistent with this prediction?

International evidence on investment rates and income per person

8.2 The Golden Rule Level of Capital

$$\begin{aligned}C^* &= (1-s)y^* \\&= y^* - sy^* \\&= f(k^*) - \delta k^*\end{aligned}$$

when $\delta = MPK$, C^* max

$sy^* = \delta k$ (equilibrium)

The Golden Rule: Introduction

- Different values of s lead to different steady states. How do we know which is the “best” steady state?
- The “best” steady state has the highest possible consumption per person: $c^* = (1-s) f(k^*)$.
- An increase in s
 - leads to higher k^* and y^* , which raises c^*
 - reduces consumption’s share of income $(1-s)$, which lowers c^* .
- So, how do we find the s and k^* that maximize c^* ?

⇒ 推导

The Golden Rule capital stock

k_{gold}^* = the **Golden Rule level of capital**,
the steady state value of k
that maximizes consumption.

To find it, first ~~express c^* in terms of k^* :~~

$$\begin{aligned} c^* &= y^* - i^* \\ &= f(k^*) - i^* \\ &= f(k^*) - \delta k^* \end{aligned}$$

In the steady state:

$$i^* = \delta k^*$$

because $\Delta k = 0$.

The Golden Rule capital stock

steady state
output and
depreciation

Then, graph $f(k^*)$ and δk^* , look for the point where the gap between them is biggest.

$$y_{gold}^* = f(k_{gold}^*)$$

steady-state
capital per
worker, k^*

The Golden Rule capital stock

$$c^* = f(k^*) - \delta k^*$$

is biggest where the slope of the production function equals the slope of the depreciation line:

$$MPK = \delta$$

steady-state
capital per
worker, k^*

The transition to the Golden Rule steady state

- The economy does NOT have a tendency to move toward the Golden Rule steady state.
- Achieving the Golden Rule requires that policymakers adjust s .
- This adjustment leads to a new steady state with higher consumption.
- But what happens to consumption during the transition to the Golden Rule?

Starting with too much capital

$$C = (1-s)y$$

If $k^* > k_{gold}^*$

then increasing c^*
requires a fall in s .

In the transition to
the Golden Rule,
consumption is
higher at all points
in time.

Starting with too little capital

$$c = f(k) - i = f(k) - sk$$

If $k^* < k_{gold}^*$

then increasing c^* requires an increase in s .

Future generations enjoy higher consumption, but the current one experiences an initial drop in consumption.

8.3 Population Growth

Population growth

- Assume the population and labor force grow at rate **n** (exogenous):

$$\frac{\Delta L}{L} = n$$

- EX: Suppose $L = 1,000$ in year 1 and the population is growing at 2% per year ($n = 0.02$).
- Then $\Delta L = nL = 0.02 \times 1,000 = 20$,
so $L = 1,020$ in year 2.

Break-even investment

- $(\delta + n)k$ = **break-even investment**,
the amount of investment necessary
to keep k constant.
- Break-even investment includes:
 - δk to replace capital as it wears out
 - nk to equip new workers with capital
(Otherwise, k would fall as the existing capital stock
is spread more thinly over a larger population of
workers.)

$$\Delta k = 0 \Leftrightarrow \frac{dk}{dt} = 0$$

- Mathematically,

$$dk/dt = d(K/L)/dt$$

$$= (1/L)(dK/dt) - (K/L^2)(dL/dt)$$

$$= (1/L)(1 - \delta K) - (K/L^2) * n L$$

$$= i - \delta k - nk$$

$$\Delta k = i - (\delta + n)k$$

The equation of motion for k

- With population growth, the equation of motion for k is:

$$\Delta k = \underbrace{sf(k)}_{\text{actual investment}} - \underbrace{(\delta + n)k}_{\text{break-even investment}}$$

actual
investment

break-even
investment

The Solow model diagram

The impact of population growth

An increase in n causes an increase in break-even investment, leading to a lower steady-state level of k .

Investment,
break-even
investment

Prediction:

- The Solow model predicts that countries with higher population growth rates will have lower levels of capital and income per worker in the long run.
- Are the data consistent with this prediction?

International evidence on population growth and income per person

The Golden Rule with population growth

To find the Golden Rule capital stock, express c^* in terms of k^* :

$$\begin{aligned} c^* &= y^* - i^* \\ &= f(k^*) - (\delta + n) k^* \end{aligned}$$

c^* is maximized when
 $MPK = \delta + n$

or equivalently,

$$MPK - \delta = n$$

扣除折旧后的MPK

In the Golden Rule steady state, the marginal product of capital net of depreciation equals the population growth rate.

International evidence on investment rates and income per person

Mankiw, *Macroeconomics*, 10e, © 2019 Worth Publishers

Alternative perspectives on population growth

The Malthusian Model (1798)

- Predicts population growth will outstrip the Earth's ability to produce food, leading to the impoverishment of humanity.
- Since Malthus, world population has increased sixfold, yet living standards are higher than ever.
- Malthus neglected the effects of technological progress.

Alternative perspectives on population growth

The Kremerian Model (1993)

- Posits that population growth contributes to economic growth.
- More people = more geniuses, scientists & engineers, so faster technological progress.
- Evidence, from very long historical periods:
 - As world pop. growth rate increased, so did rate of growth in living standards
 - Historically, regions with larger populations have enjoyed faster growth.

CHAPTER SUMMARY

1. The Solow growth model shows that, in the long run, a country's standard of living depends:
 - positively on its saving rate
 - negatively on its population growth rate
2. An increase in the saving rate leads to:
 - higher output in the long run
 - faster growth temporarily
 - but not faster steady-state growth

CHAPTER SUMMARY

3. If the economy has more capital than the Golden Rule level, then reducing saving will increase consumption at all points in time, making all generations better off.

If the economy has less capital than the Golden Rule level, then increasing saving will increase consumption for future generations, but reduce consumption for the present generation.

Exercise

- 2. In the discussion of German and Japanese postwar growth, the text describes what happens when part of the capital stock is destroyed in a war. **By contrast, suppose that a war does not directly affect the capital stock, but that casualties reduce the labor force.** Assume the economy was in a steady state before the war, the saving rate is unchanged, and the rate of population growth after the war is the same as it was before.

- a. What is the immediate impact of the war on total output and on output per person?
- b. What happens subsequently to output per worker in the postwar economy? Is the growth rate of output per worker after the war smaller or greater than it was before the war?

$$Y = F(K, L) \quad L \downarrow$$

$$y = f(k) \quad k = \frac{K}{L} \uparrow$$

Same

Exercise

- **5.** Use the graph to find what happens to steady-state capital per worker and income per worker in response to each of the following exogenous changes.
- **a.** A change in consumer preferences increases the saving rate.
- **b.** A change in weather patterns increases the depreciation rate.
- **c.** Better birth-control methods reduce the rate of population growth.
- **d.** A one-time, permanent improvement in technology increases the amount of output that can be produced from any given amount of capital and labor.
