

# CHAPTER 5

## Inflation: Its Causes, Effects, and Social Costs

Presentation Slides

# ■ Macroeconomics

■ *N. Gregory Mankiw*

# IN THIS CHAPTER, YOU WILL LEARN:

- The classical theory of inflation
  - causes
  - effects
  - social costs
- “Classical”—assumes prices are flexible & markets clear
- Applies to the long run

$$\left(\frac{M}{P}\right)^d = kY$$

{ 货币数量论 (Fisher)  $M\bar{V} = P \cdot Y$   $\%M \approx \%P + \%Y$

| 流动性偏好理论 (Keynes)  $\left(\frac{M}{P}\right)^d = L(i, Y)$

$MV = PY \Rightarrow V = \frac{Y}{\frac{M}{P}} = \frac{Y}{L(i, Y)}$   $i \uparrow V \uparrow$

## 5.1 The Quantity Theory of Money

貨幣數量論

# The quantity theory of money

- A simple theory linking the inflation rate to the growth rate of the money supply.
- Begins with the concept of **velocity**...

# Velocity

- Basic concept: the rate at which money circulates
- Definition: the number of times the average dollar bill changes hands in a given time period
- Example: In 2015,
  - \$500 billion in transactions
  - money supply = \$100 billion
  - The average dollar is used in five transactions in 2015
  - So, velocity = 5

# Velocity (*continued*)

- This suggests the following definition:

$$V = \frac{T}{M}$$

where

***V*** = velocity

***T*** = value of all transactions

***M*** = money supply

# Velocity (*continued*)

- Use nominal GDP as a proxy for total transactions.

Then,

$$V = \frac{P \times Y}{M}$$

where

$P$  = price of output

$Y$  = quantity of output

$P \times Y$  = value of output

$\frac{\text{nominal}}{\text{real}} = \text{deflator}$

$\text{deflator} \times \text{real} = \text{nominal}$

(GDP deflator)

~~(real GDP)~~

(nominal GDP)

# The quantity equation

- The **quantity equation**

$$M \times V = P \times Y$$

follows from the preceding definition of velocity.

- It is an *identity*:  
it holds by definition of the variables.

# Money demand and the quantity equation

- $M/P$  = **real money balances**, the purchasing power of the money supply.

- A simple money demand function:

$$(M/P)^d = kY$$

where

$k$  = how much money people wish to hold for each dollar of income.

( $k$  is exogenous)

$$\left(\frac{M}{P}\right)^s = \frac{Y}{V} \Rightarrow kY = \frac{Y}{V} \Rightarrow k = \frac{1}{V}$$

# Money demand and the quantity equation

- Money demand:  $(M/P)^d = kY$
- Quantity equation:  $M \times V = P \times Y$
- The connection between them:  $k = 1/V$
- When people hold lots of money relative to their incomes ( $k$  is large), money changes hands infrequently ( $V$  is small).

# Back to the quantity theory of money

- Starts with quantity equation
- Assumes  $V$  is constant & exogenous:  $V = \bar{V}$

Then, quantity equation becomes:

$$M \times \bar{V} = P \times Y$$

# The quantity theory of money (continued)

$$M \times \bar{V} = P \times Y$$

How the price level is determined:

- With **V** constant, the money supply determines nominal GDP ( $P \times Y$ ).
- Real GDP is determined by the economy's supplies of K and L and the production function (Chapter 3).
- The price level is  
 $P = (\text{nominal GDP})/(\text{real GDP}).$

# The quantity theory of money (continued)

- *Recall from Chapter 2:*  
The growth rate of a product equals the sum of the growth rates.
- The quantity equation in growth rates:

$$\frac{\Delta \mathbf{M}}{\mathbf{M}} + \frac{\Delta \mathbf{V}}{\mathbf{V}} = \frac{\Delta \mathbf{P}}{\mathbf{P}} + \frac{\Delta \mathbf{Y}}{\mathbf{Y}}$$

The quantity theory of money assumes  $\mathbf{V}$  is constant, so  $\frac{\Delta \mathbf{V}}{\mathbf{V}} = 0$ .

# The quantity theory of money (continued)

$\pi$  (Greek letter *pi*)  
denotes the **inflation rate**

$$\pi = \frac{\Delta P}{P}$$

The result from the  
preceding slide:

$$\frac{\Delta M}{M} = \frac{\Delta P}{P} + \frac{\Delta Y}{Y}$$

Solve this result  
for  $\pi$ :

$$\pi = \frac{\Delta M}{M} - \frac{\Delta Y}{Y}$$

# The quantity theory of money (continued)

$$\pi = \frac{\Delta M}{M} - \frac{\Delta Y}{Y}$$

- Normal economic growth requires a certain amount of money supply growth to facilitate the growth in transactions.
- Money growth in excess of this amount leads to inflation.

# The quantity theory of money (continued)

$$\pi = \frac{\Delta M}{M} - \frac{\Delta Y}{Y}$$

$\Delta Y/Y$  depends on growth in the factors of production and on technological progress

(all of which we take as given, for now). *(real GDP)*

*Hence, the quantity theory predicts  
a one-for-one relation between  
changes in the money growth rate and  
changes in the inflation rate.*

# Confronting the quantity theory with data

The quantity theory of money implies:

1. Countries with higher money growth rates should have higher inflation rates.
2. The long-run trend in a country's inflation rate should be similar to the long-run trend in the country's money growth rate.

*Are the data consistent with these implications?*

铸币税

## 5.2 Seigniorage: The Revenue from Printing Money

# Seigniorage

- To spend more without raising taxes or selling bonds, the govt can print money.
- The “revenue” raised from printing money is called **seigniorage**.  
(pronounced SEEN-your-idge).
- The **inflation tax**:  
Printing money to raise revenue causes inflation.  
Inflation is like a tax on people who hold money.

## 5.3 Inflation and Interest Rates

# Inflation and interest rates

- Nominal interest rate,  $i$   
not adjusted for inflation
- Real interest rate,  $r$   
adjusted for inflation:

$$r = i - \pi$$

# The Fisher effect

$$i = r + E\pi$$

- The Fisher equation:  $i = r + \pi$
- Chapter 3:  $\overset{\text{Saving} = \text{Investment}}{\underline{S} = \underline{I}}$  determines  $r$ .
- Hence, an increase in  $\pi$  causes an equal increase in  $i$ .
- This one-for-one relationship is called the **Fisher effect**.

## NOW YOU TRY

### Applying the theory

Suppose  $V$  is constant,  $M$  is growing 5% per year,  $Y$  is growing 2% per year, and  $r = 4$ .

- a. Solve for  $i$ .
- b. If the Fed increases the money growth rate by 2 percentage points per year, find  $\Delta i$ .
- c. Suppose the growth rate of  $Y$  falls to 1% per year.
  - What will happen to  $\pi$ ?
  - What must the Fed do if it wishes to keep  $\pi$  constant?

# ANSWERS

## Applying the theory

$V$  is constant,  $M$  grows 5% per year,  
 $Y$  grows 2% per year,  $r = 4$ .

a. First, find  $\pi = 5 - 2 = 3$ .

Then, find  $i = r + \pi = 4 + 3 = 7$ .

b.  $\Delta i = 2$ , same as the increase in the money growth rate.

c. If the Fed does nothing,  $\Delta\pi = 1$ .

To prevent inflation from rising, the Fed must  
reduce the money growth rate by 1 percentage point per year.

# Two real interest rates

Notation:

- $\pi$  = actual inflation rate  
(not known until after it has occurred)
- $E\pi$  = expected inflation rate

Two real interest rates:

- $i - E\pi = \text{ex ante real interest rate}$ :  
the real interest rate people expect at the time  
they buy a bond or take out a loan
- $i - \pi = \text{ex post real interest rate}$ :  
the real interest rate actually realized

## 5.4 The Nominal Interest Rate and the Demand for Money

# Money demand and the nominal interest rate

- In the quantity theory of money, the demand for real money balances depends only on real income  $Y$ .
- Another determinant of money demand: the nominal interest rate,  $i$ .
  - the opportunity cost of holding money (instead of bonds or other interest-earning assets).
- So, money demand depends negatively on  $i$ .

凯恩斯：流动性偏好理论

# The money demand function

$$(\mathbf{M}/\mathbf{P})^d = \mathbf{L}(\mathbf{i}, \mathbf{Y})$$

$(\mathbf{M}/\mathbf{P})^d$  = real money demand, depends

- negatively on  $\mathbf{i}$

$\mathbf{i}$  is the opp. cost of holding money

- positively on  $\mathbf{Y}$

higher  $\mathbf{Y}$  increases spending on g&s,  
so increases need for money

(“ $\mathbf{L}$ ” is used for the money demand function  
because money is the most liquid asset.)

# The money demand function

$$\begin{aligned} (\mathbf{M}/\mathbf{P})^d &= \mathbf{L}(\mathbf{i}, \mathbf{Y}) \\ &= \mathbf{L}(\mathbf{r} + E\pi, \mathbf{Y}) \end{aligned}$$

When people are deciding whether to hold money or bonds, ~~they don't know what inflation will turn out to be.~~

Hence, the nominal interest rate relevant for money demand is  $\mathbf{r} + E\pi$ .

# Equilibrium

$$\frac{M}{P} = L(r + E\pi, Y)$$

The supply of real  
money balances

Real money  
demand

## ***What determines what?***

$$\frac{M}{P} = L(r + E\pi, Y)$$

<u>variable</u>	<u>how determined (<i>in the long run</i>)</u>
$M$	exogenous (the Fed)
$r$	adjusts to ensure $S = I$
$Y$	$\frac{M}{P} = L(i, Y)$

$P$  adjusts to ensure  $\bar{Y} = F(\bar{K}, \bar{L})$

# How $P$ responds to $\Delta M$

$$\frac{M}{P} = L(r + E\pi, Y)$$

- For given values of  $r$ ,  $Y$ , and  $E\pi$ ,  
a change in  $M$  causes  $P$  to change by the same percentage—just like in the quantity theory of money.

## ***What about expected inflation?***

- Over the long run, people don't consistently over- or under-forecast inflation, so  $E\pi = \pi$  on average.
- In the short run,  $E\pi$  may change when people get new information.
- *E.g.:* The Fed announces it will increase  $M$  next year. People will expect next year's  $P$  to be higher, so  $E\pi$  rises.
- This affects  $P$  now, even though  $M$  hasn't changed yet...

## How $P$ responds to $\Delta E\pi$

$$\frac{M}{P} = L(r + E\pi, Y)$$

- For given values of  $r$ ,  $Y$ , and  $M$ ,

$\uparrow E\pi \Rightarrow \uparrow i$  (the Fisher effect)

$\Rightarrow \downarrow (M/P)^d$

$\Rightarrow \uparrow \underline{P}$  to make  $(M/P)$  fall  
to re-establish eq'm

## **5.5 The Social Costs of Inflation**

# The classical view of inflation

- *The classical view:*

A change in the price level is merely a change in the units of measurement.

*Then, why is inflation  
a social problem?*

## NOW YOU TRY

# Discussion Question

### *Why is inflation bad?*

- What costs does inflation impose on society?  
List all the ones you can think of.
- Focus on the long run.
- Think like an economist.

# A common misperception

- Common ~~misperception~~:  
*inflation reduces real wages*
- This is true only in the short run, when nominal wages are fixed by contracts.
- (Chapter 3) In the long run, the real wage is determined by labor supply and the marginal product of labor, not the price level or inflation rate.
- Consider the data . . .

# The CPI and average hourly earnings, 1965–2015

# The social costs of inflation

...fall into two categories:

1. costs when inflation is expected
2. costs when inflation is different than people had expected

# The costs of expected inflation:

## 1. Shoeleather Cost

- Definition: the costs and inconveniences of reducing money balances to avoid the inflation tax.
- If  $\pi$  increases,  $i$  increases (why?), so people reduce their real money balances.
- Remember: In long run, inflation does not affect real income or real spending.
- So, same monthly spending but lower average money holdings means more frequent trips to the bank to withdraw smaller amounts of cash.

# The costs of expected inflation:

## 2. Menu Costs

- Definition: The costs of changing prices.
- Examples:
  - cost of printing new menus
  - cost of printing & mailing new catalogs
- The higher is inflation, the more frequently firms must change their prices and incur these costs.

# The costs of expected inflation:

## 3. Relative Price Distortions

- Firms facing menu costs change prices infrequently.
- Example:  
A firm issues new catalog each January.  
As the general price level rises throughout the year, the firm's relative price will fall.
- Different firms change their prices at different times, leading to relative price distortions . . .  
. . . causing microeconomic inefficiencies in the allocation of resources.

# The costs of expected inflation:

## 4. Unfair Tax Treatment

Some taxes are not adjusted to account for inflation, such as the capital gains tax.

Example:

- Jan 1: you buy \$10,000 worth of Apple stock
- Dec 31: you sell the stock for \$11,000, so your nominal capital gain is \$1,000 (10%).
- Suppose  $\pi = 10\%$  during the year. Your real capital gain is \$0.
- Yet, you must pay taxes on your \$1,000 nominal gain!

# The costs of expected inflation:

## 5. General Inconvenience

- Inflation makes it harder to compare nominal values from different time periods.
- This complicates long-range financial planning.

# The cost of *unexpected* inflation:

## Arbitrary Redistribution of Purchasing Power

- Many long-term contracts not indexed, but based on  $E\pi$ .  $r = i - E\pi$
- If  $\pi$  turns out different from  $E\pi$ , then some gain at others' expense.

Example: borrowers & lenders (还债时实际通胀高)

- If  $\pi > E\pi$ , then  $(i - \pi) < (i - E\pi)$  对借款人好  
and purchasing power is transferred from lenders to borrowers.
- If  $\pi < E\pi$ , then purchasing power is transferred from borrowers to lenders.

# The cost of high inflation:

## Increased Uncertainty

- When inflation is high, it's more variable and unpredictable:  
 $\pi$  turns out different from  $E\pi$  more often,  
and the differences tend to be larger,  
*though not systematically positive or negative.*
- So, arbitrary redistributions of wealth more likely.
- This increases uncertainty, making risk-averse people worse off.

# One *benefit* of inflation

- Nominal wages are rarely reduced, even when the equilibrium real wage falls.

**This hinders labor market clearing.**

- Inflation allows the real wages to reach equilibrium levels without nominal wage cuts.
- Therefore, ~~moderate~~ inflation improves the functioning of labor markets.

## 5.6 Hyperinflation

# Hyperinflation

- Common definition:  $\pi \geq 50\%$  per month
- All the costs of moderate inflation described above become **HUGE** under hyperinflation.
- Money ceases to function as a store of value, and may not serve its other functions (unit of account, medium of exchange).
- People may conduct transactions with barter or a stable foreign currency.

# What causes hyperinflation?

- Hyperinflation is caused by excessive money supply growth.
- When the central bank prints money, the price level rises.
- If it prints money rapidly enough, the result is hyperinflation.

## A few examples of hyperinflation

<b><i>country</i></b>	<b><i>period</i></b>	<b><i>CPI Inflation % per year</i></b>	<b><i>M2 Growth % per year</i></b>
Israel	1983-85	338%	305%
Brazil	1987-94	1,256	1,451
Bolivia	1983-86	1,818	1,727
Ukraine	1992-94	2,089	1,029
Argentina	1988-90	2,671	1,583
Dem. Republic of Congo / Zaire	1990-96	3,039	2,373
Angola	1995-96	4,145	4,106
Peru	1988-90	5,050	3,517
Zimbabwe	2005-07	5,316	9,914

# Why governments create hyperinflation

- When a government cannot raise taxes or sell bonds, it must finance spending increases by printing money.
- In theory, the solution to hyperinflation is simple: stop printing money.
- In the real world, this requires drastic and painful fiscal restraint.

## **5.7 Conclusion: The Classical Dichotomy**

# The classical dichotomy

***Real variables***: Measured in physical units—quantities and relative prices, *for example*:

- quantity of output produced
- real wage: output earned per hour of work
- real interest rate: output earned in the future by lending one unit of output today

***Nominal variables***: Measured in money units, e.g.,

- nominal wage: Dollars per hour of work.
- nominal interest rate: Dollars earned in future by lending one dollar today.
- the price level: The amount of dollars needed to buy a representative basket of goods.

# The classical dichotomy

- Recall: Real variables were explained in Chapter 3, nominal ones in Chapter 5.
- ***Classical dichotomy***: the theoretical separation of real and nominal variables in the classical model, which implies nominal variables do not affect real variables.
- ***Neutrality of money***: Changes in the money supply do not affect real variables.

In the real world, money is approximately neutral in the long run.

# CHAPTER SUMMARY

---

- Velocity: the ratio of nominal expenditure to money supply, the rate at which money changes hands
- Quantity theory of money
  - assumes velocity is constant
  - concludes that the money growth rate determines the inflation rate
  - applies in the long run
  - consistent with cross-country and time-series data

# CHAPTER SUMMARY

---

- Nominal interest rate
  - equals real interest rate + inflation rate
  - the opp. cost of holding money
- Fisher effect: Nominal interest rate moves one-for-one with expected inflation.
- Money demand 流动性偏好理论
  - depends only on income in the quantity theory
  - also depends on the nominal interest rate
  - if so, then changes in expected inflation affect the current price level

# CHAPTER SUMMARY

---

## Costs of inflation

- *Expected inflation*  
shoeleather costs, menu costs,  
tax & relative price distortions,  
inconvenience of correcting figures for inflation
- *Unexpected inflation*  
all of the above plus arbitrary redistributions of  
wealth between debtors and creditors

# CHAPTER SUMMARY

---

## Hyperinflation

- caused by rapid money supply growth when money printed to finance govt budget deficits
- stopping it requires fiscal reforms to eliminate govt's need for printing money

# CHAPTER SUMMARY

---

## Classical dichotomy

- In classical theory, money is neutral—does not affect real variables.
- So, we can study how real variables are determined w/o reference to nominal ones.
- Then, money market eq'm determines price level and all nominal variables.
- Most economists believe the economy works this way in the long run.

# Exercises

4. Suppose that the money demand function takes the form  $(M/P)^d = L(i, Y) = Y/(5i)$ .

- a. If output grows at rate  $g$  and the nominal interest rate is constant, at what rate will the demand for real balances grow?
- b. What is the velocity of money in this economy?
- c. If inflation and nominal interest rates are constant, at what rate, if any, will velocity grow?

- **d.** How will a permanent (once-and-for-all) increase in the level of interest rates affect the level of velocity? How will it affect the subsequent growth rate of velocity?
- **e.** If the central bank wants to achieve a long-run target inflation rate of  $\pi^i$ , at what rate should the money supply grow?
